## **CONVERSION FACTORS AND ABBREVIATED WATER-QUALITY UNITS**

| Multiply                      | By     | To Obtain        |
|-------------------------------|--------|------------------|
| inch (in.)                    | 25.4   | millimeter       |
| foot (ft)                     | 0.3048 | meter            |
| acre                          | 0.4048 | hectare          |
| square mile ( $\text{mi}^2$ ) | 2.590  | square kilometer |
| pound (lb)                    | 453.6  | gram             |
| ton (short)                   | 0.9072 | megagram (mg)    |

**Abbreviated water-quality units used in this report:** Chemical concentrations and water temperature are given in metric units. Chemical concentration is given in milligrams per liter (mg/L) or micrograms per liter ( $\mu\text{g}/\text{L}$ ). Milligrams per liter is a unit expressing the concentration of chemical constituents in solution as weight (milligrams) of solute per unit volume (liter) of water. One thousand micrograms per liter is equivalent to one milligram per liter. For concentrations less than 7,000 mg/L, the numerical value is the same as for concentrations in parts per million. Other units of measurement used in this report are microsiemens per centimeter at 25°Celsius ( $\mu\text{S}/\text{cm}$ ).

# Temperature, pH, Conductance, and Dissolved Oxygen in Cross Sections of 11 Lake Michigan Tributaries, 1994–95

By David W. Hall<sup>1</sup>, Thomas E. Behrendt<sup>2</sup>, and Peter E. Hughes<sup>1</sup>

## Abstract

Temperature, pH, conductance, and dissolved oxygen data were collected along cross sections at 11 major tributaries to Lake Michigan from April 1994 through October 1995 as part of the U.S. Geological Survey Lake Michigan Tributary Monitoring Project. Eleven tributary monitoring stations were installed near their points of discharge into Lake Michigan, and were located sufficiently upstream to minimize mixing of lake and tributary water during most flow conditions. A total of 405 samples were collected from the 11 tributaries. The Grand Calumet, Kalamazoo, and Pere Marquette Rivers were generally well mixed throughout the sampling period. The Sheboygan, Menominee, Manistique, Muskegon, Grand, and St. Joseph Rivers were generally well mixed during winter months and stratified with respect to temperature and conductance in summer months. The Milwaukee River, and to a lesser extent the Fox River, were found to be poorly mixed at irregular intervals throughout the sampling period.

## INTRODUCTION

Temperature, pH, conductance, and dissolved oxygen data were collected along cross sections at 11 major tributaries to Lake Michigan from April 1994 through October 1995 as part of the U.S. Geological Survey (USGS) Lake Michigan Tributary Monitoring Project (LMTMP). This project was part of the U.S. Environmental Protection Agency's (USEPA) Lake Michigan Mass Balance Project (USEPA Great Lakes National Program Office, 1995; Blume, 1997a, 1997b, 1997c) and was conducted by the USGS in cooperation with the Wisconsin Department of Natural Resources, the Michigan Department of Environmental Quality, the Wis-

consin State Laboratory of Hygiene, and the University of Wisconsin Water Chemistry Program. The primary objective of the LMTMP was to provide tributary contaminant-loading data for input into the USEPA's Lake Michigan Mass Balance model.

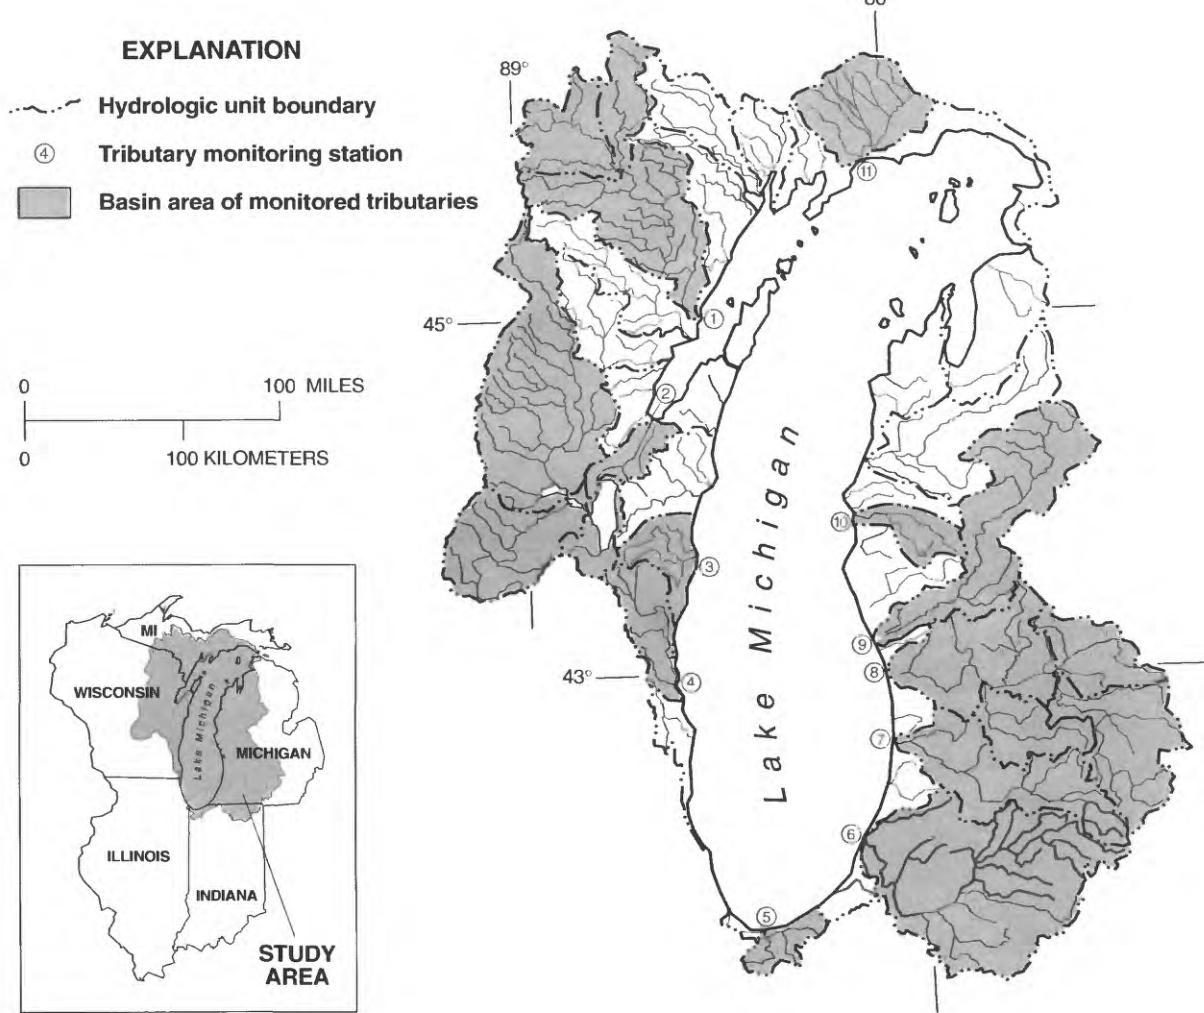

The primary objective of this report is to describe ancillary field data collected during sampling. These data may be of interest because they illustrate spatial and temporal heterogeneities that may be considered when constructing a mass-balance model or designing a representative water-quality-sampling program on rivers.

## DISCHARGE MEASUREMENT AND RIVER SAMPLING

Eleven tributary monitoring stations were installed near their points of discharge into Lake Michigan (fig. 1; table 1), and were located sufficiently upstream to minimize mixing of lake and tributary water during most flow conditions (Holmstrom and others, 1995, 1996; Blumer and others, 1995, 1996; Stewart and others, 1995, 1996). Discharge was measured using traditional stage/discharge techniques at the Manistique, Pere Marquette, and Kalamazoo Rivers in Michigan. Acoustic velocity meters were installed to measure discharge at the Muskegon, Grand, and St. Joseph Rivers in Michigan, at the Grand Calumet River in Indiana, and on the Milwaukee, Sheboygan, Fox, and Menominee Rivers in Wisconsin. A total of 405 samples (including quality control blanks) were collected from the 11 tributaries (appendix 1). To reduce the error associated with load calculations, sampling was deliberately biased toward high-flow conditions (more than 20 percent of samples were collected at times of discharge above the 20 percent exceedance) at each site (Dolan, 1981).

## **SPATIAL AND TEMPORAL VARIATION IN TEMPERATURE, pH, CONDUCTANCE, AND DISSOLVED OXYGEN IN RIVER CROSS SECTIONS**

Subsampling locations were determined by sampling in the center of three estimated areas of equal flow across each river, approximately at quarterpoints. At each of these three points, a hydrolab was used to measure temperature, pH, conductance, and dissolved oxygen at 0.2 and 0.8 times the river depth prior to the collection of samples for water-quality analysis. All of these data are presented in appendix 2. The Pere Marquette and Kalamazoo Rivers were sufficiently shallow at the sampled cross section that water was assumed to be well mixed vertically, and therefore data were collected and rivers were sampled at only one depth in each of the three equal flow areas.

Qualitative analysis of the data presented in appendix 2 indicate that the Kalamazoo, Pere Marquette, and Grand Calumet/Indiana Harbor Rivers may be classified as being well mixed throughout the year. The Sheboygan, Menominee, Manistique, Muskegon, Grand, and St. Joseph Rivers were generally well mixed during winter months and stratified with respect to temperature and conductance in summer months. The Milwaukee River, and to a lesser extent the Fox River, were found to be poorly mixed at irregular intervals throughout the year.
